TITLE: A bent dipole antenna with a counterweight. Class 21, No. 185971

SOURCE: Izobret prom obraz tov zn, no. 18, 1966, 56

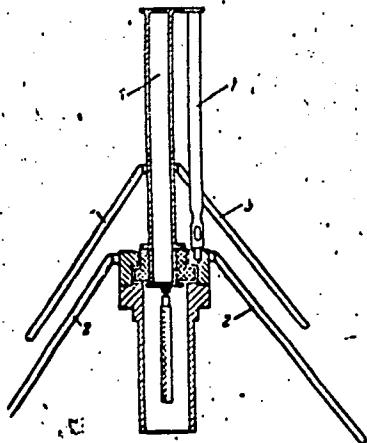

TOPIC TAGS: dipole antenna, bandwidth expansion

ABSTRACT: This Author's Certificate introduces a bent dipole antenna with a counter-weight. The unit consists of an asymmetric bent dipole equipped on the lower end with a quarter-wave inclined multiple-rod counterweight. The working frequency band is expanded by connecting a second counterweight to the supply rod made up of rods tuned to the upper limit of the frequency range.

TITLE: Explosion welding

PERIODICAL: Svarochnoye proizvodstvo, no. 5, 1962, 3 - 6

TEXT: The possibility of explosion-welding similar and dissimilar metals [steels T.3. (St.3) + St.3; St.3 + 1X18H9T (1Kh18N9T), M3 + M3; OT4 + OT4; OT4 + M3; 1Kh18N9T + M3 and 1Kh18N9T + A₁H(ADN)] was experimentally investigated. (See Figure 1). Plates 150 - 200 mm long, 20 - 40 mm wide and 1.5 - 15 mm and 1.5 - 4 mm thick were welded. The variable values were: distance h between the plate surfaces, angle α between the plates along the longitudinal axis of the samples, and the charge height of the explosive. Explosion welding makes it possible to obtain weld joints in the solid phase without the formation of intermediate chemical components between dissimilar metals and alloys. In explosion welding, the joint is produced under the effect of the scattering

Card 1/3

Explosion welding

S/135/62/000/005/001/007
A006/A101

explosive detonation products upon the surfaces to be welded which are arranged to each other at a certain angle. During their collision, a cumulative jet is being formed, and the motion of the movable plate along the fixed one causes the tangential shift of their surface layers. The tangential discontinuity of speed which then occurs is accompanied by an increase of disturbances. The jet destroys and carries away oxide films and other non-metallic inclusions from the surfaces to be joined. The disturbances, additionally to tangential shifts, cause the joint formation of "waves" on the surfaces to be joined at the collision points; they are thereby approached to distances which are necessary for the arising of metallic bonds between the parts, and the junction surface is thus increased. The explosive type is an important factor in explosion welding; best results were obtained with low-density granular materials such as Hexogen, etc. Explosion welding can be used in the manufacture of blanks for bimetal rolling, cladding of structural steel surfaces with metals and alloys, having particular physical and chemical properties; and for welding dissimilar metal blanks and parts. The authors thank Academician M. A. Lavrent'yev for his assistance. There are 9 figures, 1 table and 9 references: 6 Soviet-bloc and 3 non-Soviet-bloc.

AUTHOR: Bichenkov, Ye. I. (Novosibirsk)

TITLE: The effect of finite conductivity on the generation of strong magnetic fields by the sudden collapse of conducting shells

SOURCE: Zhurnal prikladnoy mekhaniki i tekhnicheskoy fiziki, no. 6, 1964, 3-5

TOPIC TAGS: strong magnetic field, finite conductivity, uniform magnetic field, superconductor, conducting shell, implosion

ABSTRACT: A general statement is given of the problem of explaining phenomena taking place during the collapse [implosion] of shells made of superconducting material, but also taking into account field diffusion into the conductor, conductor heating, possible evaporation, and change in electric conductivity associated with this and other effects. Phenomena connected with the presence of finite conductivity are also investigated. Starting with the assumption that conductivity is constant, the limiting field and the effective depth of field penetration into the conductor are calculated for the case of the constriction of a uniform magnetic field by two flat, parallel surfaces moving towards each other at constant velocity.

Card 1/2

L 43724-65

ACCESSION NR: AP5008493

The calculation given for field penetration into the conductor shows the essential difference in the solution of the problem for a superconductor and for a conductor with finite conductivity, and from the mathematical point of view consists in the degeneration of the integral equation describing the field constriction process.

Vinogradov, Candidate of Technical Sciences; N. N. Chaytik, Professor; F. P. Dushkov, Professor; I. A. Charygina, Professor; V. N. Dakhov, Professor; G. M. Fomichev, Professor.		
PURPOSE: This collection of articles is intended for specialists in the petroleum and gas industry. It will also be of interest to scientific research institutes, teachers and students of universities, and symbolic gas problems connected with natural gas production. A number of articles are devoted to the study of regional oil and gas-bearing zones, the organogenic beds underlying the Volga-Ural oil and gas-bearing regions, the geology of the Caspian depression, seismic prospecting, oil well logging, development of oil and gas fields, petroleum engineering, development of oil and gas fields, their physico-chemical characteristics, and their possible use in the oil and gas industry, the production of organic catalysts, the application of ion exchange technology, the improvement of heavy petroleum residues, the solid wastes on properties of lube oil production, (including a number of photographs, tables, flow sheets, and diagrams. The book contains those relating to coal, gasification and conversion of heavy petroleum residues over a catalyst bed, catalysts for catalytic cracking of heavy petroleum residues. References accompany individual articles.

TITLE: Organophosphorus preparations and wilt disease of cotton plants

SOURCE: Zashchita rasteniy ot vrediteley i bolezney, no. 9, 1965, 26

TOPIC TAGS: insecticide, plant disease, plant disease control, plant growth

ABSTRACT: The effect of organophosphorus preparations on verticilliaceous wilt disease in cotton plants was studied in the experimental base of the Institut zashchity rasteniy SoyuzNIKhi (Institute for Plant Protection, SoyuzNIKhi). The experiments took into account the effect of the preparations on growth, the appearance of blooming and ripening phases, disease incidence rate, the harvest of the cotton, and field germination. By the end of the season the incidence rate had increased 16 fold. The greatest effect was due to Meta-Systox processing at the beginning of budding. Starting in 1963, only methyl-mercaptophos (1 kg/hectare) was used, since it stimulates the growth of plants. This preparation, used in the earlier phase of the development of the cotton plant, does not promote wilt disease, and in the budding stage increases the quantity of diseased plants (by 16 — 20% as compared to the control), but does not decrease the harvest. The seeds processed by this preparation lose their germinating capacity somewhat (49. 9% vs 71% in the control). The blooming stage appeared 6 — 7 days later than in the control.

TITLE: Further remarks concerning two mechanisms of photostimulated electron emission from ionic crystals /Report, Fourteenth All-Union Conference on Luminescence (Crystal Phosphors) held at Riga, 16-23 Sept. 1965/

SOURCE: AN SSSR. Izvestiya. Seriya fizicheskaya, v. 30, no. 9, 1966, 1448-1450

TOPIC TAGS: luminescent crystal, alkali halide, secondary electron emission, photoelectric effect, luminescence center, F band, SIMULATED EMISSION, PHOTOELECTRON

ABSTRACT: The following two mechanisms for photostimulated electron emission from alkali halide crystals are briefly discussed: 1) direct photoionization of an F center with the escape from the crystal of the resulting energetic photoelectron) and 2) photothermal ionization of a center and escape from the crystal as a result of thermal fluctuations of the thermal electron thus produced. The potential barriers W against escape of an electron from alkali halide crystals are calculated as the difference between the photoelectric threshold and the width of the forbidden gap from relevant data in the literature. Values of W for NaCl and KCl were also calcu-

Card 1/2

ACC NR: AP7004969

lated from the temperature dependence of electron emission from previously x-ray irradiated crystals stimulated in the F and E bands by invoking mechanism 2). The W values found in this way were systematically lower than those calculated directly from the photoelectric threshold. It is hypothesized that this difference is due to the fact that the photoelectric effect was investigated in vacuum, whereas the emission due to stimulation in the F and E bands was measured in a gaseous atmosphere. This hypothesis was tested by measuring the photostimulated luminescence and electron emission in vacuum of x-ray or γ -ray excited KCl:Tl and KBr:Tl crystals. It was found that a maximum in the F band in the stimulation spectrum for photostimulated electron emission, which is characteristic of process 2), was present only when the measurements were made in a gaseous atmosphere (air + alcohol vapor, or methane). It is assumed that the presence of an atmosphere results in contamination of the surface and therefore in a lower value of W, which makes it possible for mechanism 2) to contribute appreciably to the electron emission. Orig. art. has: 3 figures and 1 table.

TITLE: The Determination of the ¹ Seismic Elements From Regional Instrumental Observations

PERIODICAL: Soobshch. Sakhalinsk. kompleksn. n.-i. in-ta. AS USSR, 1957, Nr 5,
pp 72 - 86

ABSTRACT: Hodographs were plotted and the structure of the earth's crust was determined on the basis of observations of the regional seismic stations tracking 26 earthquakes in Central Asia in 1949 - 1950. The epicenters were determined by the epicentral method (under the assumption that the hodograph is rectilinear), the time in the focus was determined from the hodograph of the P- and S-waves by the Vadati-method by special formulae for diffracted waves. According to the values of the initial ordinates of the linear hodographs, all the earthquakes investigated were divided into two groups, which was in accordance with the existence of two focal surfaces. The comparison of the hodographs of the earthquakes with the surfaces. Card 1/2

SOV/169-59-2-1157

The Determination of the Seismic Elements From Regional Instrumental Observations

hodographs of the explosions showed that the focus of the one of the groups is situated on the surface. In that case, the depth of the foci of the second group amounts to about 29 km. The corresponding structure of the earth's crust in Central Asia is as follows: the thickness of the granite stratum amounts to 29 km, the thickness of the basalt stratum to 16 km.

AUTHOR: Bichevskaya, L. L.

TITLE: Evaluation of the aggressiveness of petroleum products from the swelling of a rubber standard

SOURCE: Kauchuk i rezina, no. 7, 1964, 29-32

TOPIC TAGS: synthetic rubber, petroleum product aggressiveness, synthetic rubber seal, synthetic rubber swelling, petroleum aggressiveness analysis, standard swelling comparison method, swelling slide rule, NBR rubber, neoprene rubber, petroleum

ABSTRACT: The author analyzes previous methods for evaluating aggressiveness (standard liquids method, structural-group analysis, formulas relating swelling maximum and density of spatial lattice, aniline point) and discusses their shortcomings. She then selects an NBR rubber standard (SKN-26), constructs a diagram of progressively greater swelling of the standard in 22 petroleum products (less than 1% by weight for MS-20 to more than 10% for kerosene), and submits a method of evaluating aggressiveness based on similarity of variations in

Card 1/3

ACCESSION NR: AP4042340

swelling of the standard and of any serial production rubber in two different petroleum products:

$$\frac{Q'_{\infty A} - Q'_{\infty B}}{A} = \frac{Q''_{\infty A} - Q''_{\infty B}}{B}$$

where $- Q'_{\infty A}$ and $Q'_{\infty B}$ are swelling of the standard in petroleum products A and B respectively,

$Q''_{\infty A}$ and $Q''_{\infty B}$ are the same values for the product rubber under analysis. Experimental verification of the results calculated with the above formula for SKN-26 based serial production rubber in seven petroleum products at 80C showed maximum errors of 1.0 - 1.5% by weight. The method is simplified further by the use of a slide rule (illustrated), permitting rapid readings and constructed for various neoprene and NBR rubbers in relation to various petroleum products. Acceptance of the proposed parameter in technical specifications and government standards will facilitate standardization of petroleum products as to aggressiveness in relation to synthetic rubbers. Orig. art. has: 3 graphs, 1 table and 2 formulas.

AUTHOR: Bicheykin, N. I.

TITLE: Methemoglobin formation in rabbits with administration of chemical protectors against ionizing radiation

SOURCE: Radiobiologiya, v. 5, no. 2, 1965, 293-294

TOPIC TAGS: animal, rabbit, methemoglobin, blood, radioprotector, gamma-ray irradiation, single radiation dose, methemoglobinemia, sodium nitrite, paraaminopropiophenon, paraaminobutyrophenon, cysteine, beta-mercaptopropylamine, beta-mercaptoproethylamine

ABSTRACT: Experimental and control groups of male rabbits weighing 2-3 kg received intravenously the following radioprotectors: sodium nitrite (30 mg/kg), paraaminopropiophenon (30 mg/kg), paraaminobutyrophenon (30 mg/kg), l-cysteine (400 mg/kg), beta-mercaptoproethylamine (125 mg/kg), and beta-mercaptopropylamine (150 mg/kg). Then the experimental groups of animals were gamma-irradiated (EGO-2 unit, 278 r/min) with single 800 r doses. Methemoglobin levels of the blood were determined in the blood spectrophotometrically at periods of 10, 30, 60, and 180 min following radioprotector administration. Findings indicate that sodium nitrite,

Card 1/2

AC L 62114-65.

ACCESSION NR: AP5010356

paraaminopriophenon, and paraaminobutyrophenon induce considerable methemoglobinemia, of the same degree and duration for all three radioprotectors. In irradiated animals, the nature of methemoglobin formation for these three radioprotectors is essentially the same. Administration of l-cysteine, beta-mercaptopropylamine, and beta-mercaptopropylamine did not produce any statistically reliable increase of methemoglobin in the blood of control animals and tended to decrease the level in irradiated animals. With irradiation of 800 r, methemoglobin forms in the blood and after 180 min its level is 15.8/6.0% higher than the norm. Findings of this study concur with literature data on methemoglobin formation in other animals. Orig. art. has: 2 figures.
